Introduction

We studied how to model cryptographic protocols in applied pi-calculus

- but how can we formulate security properties?
- **secrecy**: the attacker should not be able to learn confidential parts of protocol messages
- **authentication**: a subtle property, which ensures that the sender and the receiver “agree” on the exchanged data and their respective roles

Secrecy

Definition

The process P preserves the **secrecy** of M iff, for all the opponents O , we have that $P \mid O$ never outputs M on a public channel.

This also covers the case where M is not directly leaked by P , but can be reconstructed by O , because O can then output M on a public channel.

Do the following processes preserve the secrecy of n ?

- $(\nu k) (\bar{c} \langle \text{senc}(n, k) \rangle)$

Secrecy

Definition

The process P preserves the **secrecy** of M iff, for all the opponents O , we have that $P \mid O$ never outputs M on a public channel.

This also covers the case where M is not directly leaked by P , but can be reconstructed by O , because O can then output M on a public channel.

Do the following processes preserve the secrecy of n ?

- $(\nu k) (\bar{c} \langle \text{senc}(n, k) \rangle)$
- $(\nu n) (\nu k) (\bar{c} \langle \text{senc}(n, k) \rangle)$

Secrecy

Definition

The process P preserves the **secrecy** of M iff, for all the opponents O , we have that $P \mid O$ never outputs M on a public channel.

This also covers the case where M is not directly leaked by P , but can be reconstructed by O , because O can then output M on a public channel.

Do the following processes preserve the secrecy of n ?

- $(\nu k) (\bar{c} \langle \text{senc}(n, k) \rangle)$
- $(\nu n) (\nu k) (\bar{c} \langle \text{senc}(n, k) \rangle)$
- $(\nu n) (\nu k) (\bar{c} \langle \text{senc}(n, k) \rangle . \bar{c} \langle k \rangle)$

Violating Secrecy

Pick the process $P \triangleq (\nu n) (\nu k) (\bar{c}\langle \text{senc}(n, k) \rangle. \bar{c}\langle k \rangle)$

The secrecy of n is violated by the following opponent:

$$O \triangleq c(x).c(y).\text{let } z = \text{sdec}(x, y) \text{ in } \bar{a}\langle z \rangle$$

We can show that:

$$\begin{aligned} P \mid O &\rightarrow (\nu n) (\nu k) (\bar{c}\langle k \rangle \mid c(y).\text{let } z = \text{sdec}(\text{senc}(n, k), y) \text{ in } \bar{a}\langle z \rangle) \\ &\rightarrow (\nu n) (\nu k) \text{let } z = \text{sdec}(\text{senc}(n, k), k) \text{ in } \bar{a}\langle z \rangle \\ &\rightarrow (\nu n) (\nu k) \bar{a}\langle n \rangle \end{aligned}$$

Strong Secrecy

Our simple definition of secrecy has two main problems:

- 1 **no implicit flows**: we have discussed that secrets can be leaked bit by bit, we can't capture that only part of the secret is revealed
- 2 **limited expressiveness**: what if the secret is a public value, like in the case of e-voting protocols?

There are also stronger definitions of secrecy in the literature, based on the notion of **observational equivalence**.

Example

A protocol run where Alice votes for Bob is observationally equivalent to a protocol run where Alice votes for Charlie.

Authentication

Authentication is harder to formulate than secrecy

- **non-injective** agreement: the parties must agree on their respective identities, their role in the protocol and the content of the message
- **injective** agreement: same as above, but the recipient must also be able to verify the freshness of the message

Example

Assume that A sends a payment order M to B . Non-injective agreement requires that B authenticates A as the sender of M . Injective agreement also ensures that B cannot accept M multiple times (no replay attacks).

Correspondence Assertions

We decorate the protocol code with **events**, also called **correspondence assertions** in traditional literature

- **begin**(A, B, M): A sends to B the message M
- **end**(A, B, M): B accepts from A the message M

We assume that the attacker's code cannot contain `end()` events

Definition

The process P satisfies **non-injective agreement** iff, for all the opponents O and runs of $P \mid O$, each `end`(A, B, M) is preceded by a `begin`(A, B, M).

We require a **distinct** `begin`(A, B, M) for injective agreement!

Example: Injective vs Non-Injective Agreement

$A \triangleq \text{begin}(a, b, M). \bar{b}\langle \text{sign}(M, K_A) \rangle$

$B \triangleq !b(x). \text{let } y = \text{ver}(x, \text{pk}(K_A)) \text{ in } \text{end}(a, b, y)$

$S \triangleq (\nu K_A) (A \mid B)$

This protocol satisfies non-injective agreement, but violates injective agreement: $O \triangleq b(x). \bar{b}\langle x \rangle. \bar{b}\langle x \rangle$

Challenge - Response Handshakes

We now study three different challenge-response schemes:

- **plain-cipher** (PC): challenge in clear, response encrypted
- **cipher-plain** (CP): challenge encrypted, response in clear
- **cipher-cipher** (CC): both challenge and response encrypted

Common idea: prove your identity by encrypting/decrypting

However, these schemes enjoy different security properties!

PC Handshake - Symmetric Key

Which authentication property is satisfied by the protocol?

PC Handshake - Symmetric Key

Which authentication property is satisfied by the protocol?

Answer: injective agreement $\text{begin}(A, B, M), \dots, \text{end}(A, B, M)$

PC Handshake - Asymmetric Key

Which authentication property is satisfied by the protocol?

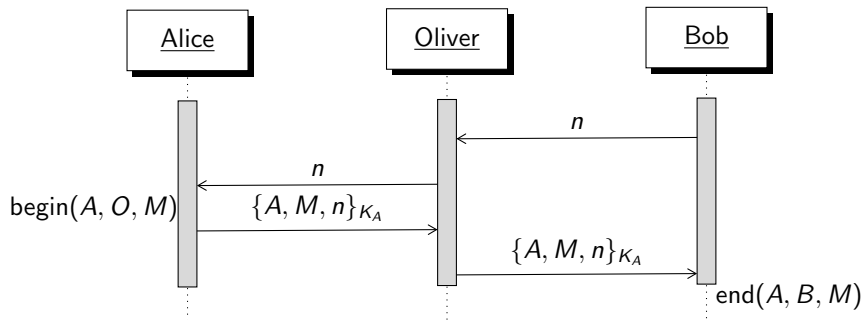

PC Handshake - Asymmetric Key

Which authentication property is satisfied by the protocol?

Answer: none! The second message is the same for Bob and Oliver!

Breaking Authentication

Fix: in the second message replace the identity of the sender A with the identity of the recipient O

CP Handshake - Symmetric Key

Which authentication properties are satisfied by the protocol?

CP Handshake - Symmetric Key

Which authentication properties are satisfied by the protocol?

Answer: non-injective agreement $\text{begin}(B, A, M), \dots, \text{end}(B, A, M)$ and injective agreement $\text{begin}(A, B, M), \dots, \text{end}(A, B, M)$

CP Handshake - Asymmetric Key

Which authentication properties are satisfied by the protocol?

CP Handshake - Asymmetric Key

Which authentication properties are satisfied by the protocol?

Answer: just injective agreement $\text{begin}(A, B, M), \dots, \text{end}(A, B, M)$, since the challenge might come from Oliver

CC Handshake - Symmetric Key

Which authentication properties are satisfied by the protocol?

CC Handshake - Symmetric Key

Which authentication properties are satisfied by the protocol?

Answer: non-injective agreement $\text{begin}(B, A, M_1), \dots, \text{end}(B, A, M_1)$ and injective agreement $\text{begin}(A, B, M_2), \dots, \text{end}(A, B, M_2)$

CC Handshake - Asymmetric Key

Which authentication properties are satisfied by the protocol?

CC Handshake - Asymmetric Key

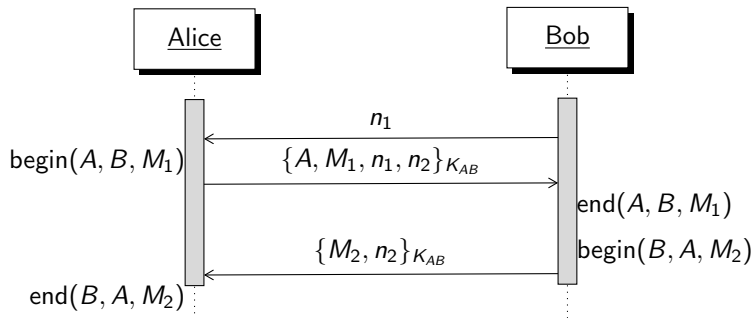

Which authentication properties are satisfied by the protocol?

Answer: just injective agreement $begin(A, B, M_2), \dots, end(A, B, M_2)$, since the challenge might come from Oliver

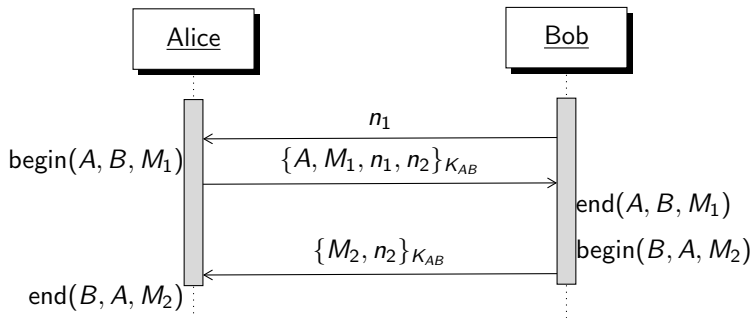

Mutual Authentication - Symmetric Key

Which authentication properties are satisfied by the protocol?

Mutual Authentication - Symmetric Key

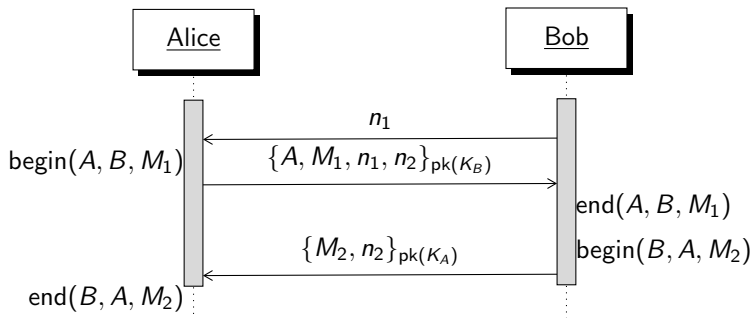

Which authentication properties are satisfied by the protocol?

Answer: injective agreement $\text{begin}(B, A, M_1), \dots, \text{end}(B, A, M_1)$ and injective agreement $\text{begin}(A, B, M_2), \dots, \text{end}(A, B, M_2)$

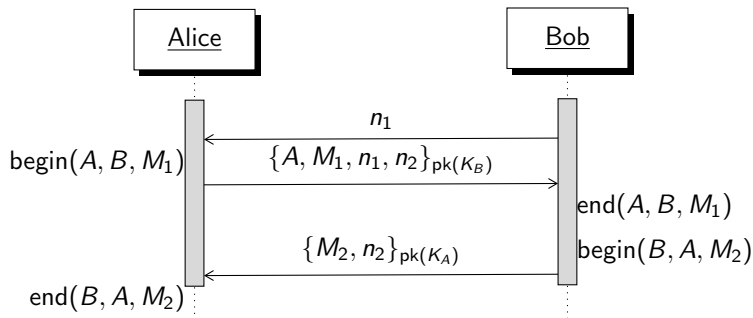

Mutual Authentication - Asymmetric Key

Which authentication properties are satisfied by the protocol?

Mutual Authentication - Asymmetric Key

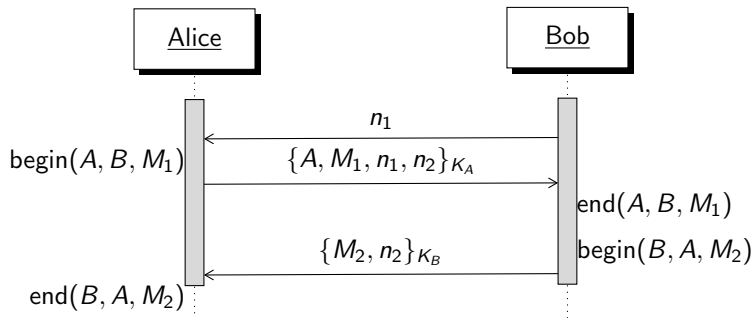

Which authentication properties are satisfied by the protocol?

Answer: just injective agreement $\text{begin}(B, A, M_2), \dots, \text{end}(B, A, M_2)$, since the first response might come from Oliver

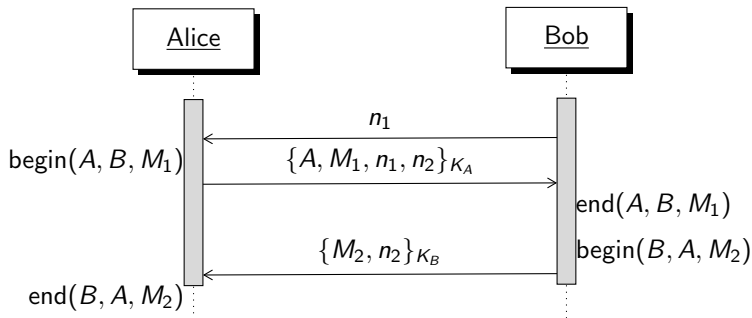

Mutual Authentication - Asymmetric Key (Revised)

Which authentication properties are satisfied by the protocol?

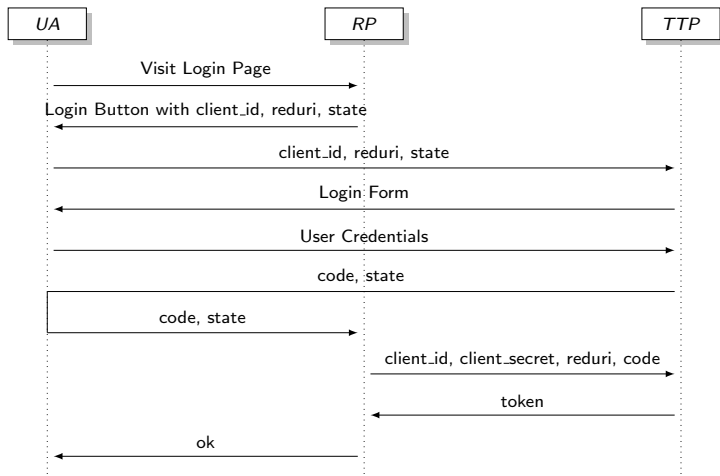

Mutual Authentication - Asymmetric Key (Revised)

Which authentication properties are satisfied by the protocol?

Answer: injective agreement $\text{begin}(B, A, M_1), \dots, \text{end}(B, A, M_1)$ and injective agreement $\text{begin}(A, B, M_2), \dots, \text{end}(A, B, M_2)$

OAuth 2.0 (Explicit Mode)

What Now?

We have shown how to formalize security properties of protocols

- showing that a property is false is “easy”: counter-example
- showing that a property is true is more complicated, since most useful security properties are **undecidable**
- very easy for humans to make mistakes, think about previous cases!
- luckily, we have **verification tools** for secrecy and authentication properties of cryptographic protocols
- next lecture: ProVerif, a state-of-the-art verification tool
